Job Market Paper

Temporary Liquidity and Firm Investment: the Large Effects from Corporate Debt Moratoria in a Time of Crisis
with Alberto Grassi and Nils Kerwien
Presentation: 2025 Annual Carey Finance Conference

Suspending loan repayments is a widely used tool to provide liquidity during crises. We exploit corporate debt moratoria as a quasi-experimental setting to study how firms invest temporary liquidity that must eventually be

repaid. We examine the take-up and real effects of the 2020 Austrian corporate debt moratorium, which required banks to postpone loan repayments for micro-enterprises. Exploiting a discontinuity in eligibility at a two-million-euro asset threshold, we document a take-up rate of 44%, well below full participation. We show that incomplete take-up reflects both pecuniary and reputational costs. Moratoria increase investment and profitability without increasing defaults once repayments resume. We estimate a marginal propensity to invest of 76 cents per euro of postponed payments. We rationalize these findings in a dynamic investment model and compare moratoria with grants, the predominant form of business support in the United States. Unlike grants, moratoria induce virtuous self-selection: only financially constrained firms with profitable investment opportunities opt in. Moratoria entail no fiscal cost, making them particularly appealing for highly indebted countries, with the caveat that the banking sector bears the policy cost if firms default.

Working Papers

Inflation and Investors
with M. Hoerova and J. Breckenfelder
Presentation: 2025 ESADE Spring Workshop, EEA 2025, CEPR Annual MEF Symposium 2025.

Using security-level holdings of bond and equity fund shares, we show how different investors respond to inflation shocks, distinguishing between cost-push ('bad") inflation and demand-driven (good") inflation. We compare flows across different fund shares - held by different investors - within the same fund. In the aggregate, bad inflation shocks lead to stagflation, hurting bond and equity funds' performance and leading to outflows. By contrast, good inflation shocks raise expected inflation when economic activity is high, hurting bonds but lifting equity. We show that aggregate responses are driven primarily by the re-balancing of Investment Funds who respond quickly and strongly to shocks. Households' response is less pronounced quantitatively but persistent. By contrast, Insurance Companies are 'steady-hand" investors, showing an overall more muted reaction to inflation shocks.

Inflation Expectations, Investment, and the Mundell-Tobin Financing Channel
with J. Mejia and A. Tagliabracci
Presentation: Dauphine Finance PhD Workshop.

We provide causal evidence that firms' investment responsiveness to inflation depends strongly on the horizon over which inflation is expected. Exploiting a randomized information treatment embedded in the Bank of Italy's Survey of Inflation and Growth Expectations, we construct a sign-adjusted instrument for exogenous shocks to expected inflation at horizons of six months, one year, two years, and three–five years. We show that total investment is increasing in the forecast horizon, but the effect is larger for tangible than intangible investment. We interpret these findings through the lens of a classic Mundell-Tobin channel. Higher inflation expectations reduce the real cost of externally financed tangible capital and stimulates investment. Intangi-

ble investment, which is primarily internally financed, rises only through its complementarity with tangibles. Our heterogeneity analyses by expectation horizon, liquidity, and leverage help rule out alternative channels, reinforcing our interpretation.

Private Credit and the Financial Accelerator
with B. Dubois and P. Rintamäki

While European firms have historically relied on bank lending, the past decade has seen a rapid expansion of private credit, which has grown at nearly twice the pace of the U.S. market. The project aims to understand how the specific collateral and control structures of private credit lending reshape credit cycles and the financial accelerator. On the one hand, private credit may attenuate the financial accelerator by limiting inefficient liquidations and fire sales during downturns. On the other hand, if large shocks impair the banking sector and restrict funding to private credit intermediaries, the resulting interlinkages may generate contagion and amplify systemic risk. From a policy perspective, the analysis speaks to how financial stability tools can accommodate private credit growth while limiting tail-risk contagion from the banking sector.
